RESEARCH INTERESTS:

Mineral processing, phenomena involved in flotation separations including surface chemistry, particle/particle interaction and particle/bubble interaction. Research has focused on fine particle flotation in a centrifugal field with the air-sparged hydrocyclone, liberation phenomena, image analysis, and the flotation chemistry of sulfide, nonsulfide, and fossil energy minerals. Flotation research includes the study of auriferous pyrite and PGM sulfide minerals, the study of phosphate and trona ore in the case of nonsulfide minerals, and the study of coal, oil sands, and oil shale in the case of fossil energy minerals. Finally, an effort in the application of x-ray CT to process engineering is in progress with the installation of a microfocus x-ray CT system at the University of Utah.

A major research effort is in progress using the microCT to provide 3D analysis of multiphase particles at a resolution of 5 to 10 microns. Research topics involving multiphase particles include; mineral exposure, mineral liberation, coal washability, particle shape, pore network structure of packed particle beds, strength of porous particle structures, caking and agglomeration, etc. The microCT analyses of particulate systems are being used as a basis for lattice Boltzmann simulation of fluid flow in porous media, micro finite element analysis of porous structures, and the evaluation of particle breakage phenomena.

Surface chemistry research activities have been concerned with the adsorption of surfactants and polymers, particularly the characterization of self-assembled monolayers and LB monolayers by FTIR/IRS and Raman spectroscopy. Recently a laboratory has been dedicated to sum frequency spectroscopy for the examination of interfacial chemistry. The spectroscopic characteristics of interfacial water are now being studied at hydrophobic surfaces together with the development of advanced water-repellent coatings.

Surface force measurements are being accomplished by Atomic Force Microscopy using the colloidal probe technique. Considerable surface chemistry research efforts are now based on analysis by atomic force microscopy (AFM) and advanced instrumentation has been accommodated in the AFM laboratory. Recent accomplishments include the in-situ imaging of surface micelle structures and macromolecules. Equally important is the research on surface force measurements using the colloidal probe technique including the examination of hydrophobic forces and the effect of nanoscale roughness.

The complimentary results from surface spectroscopy, AFM surface force measurements, and AFM surface imaging are being analyzed using molecular dynamics simulation (MDS).

Hydrometallurgy, specifically the physical chemistry of leaching, cementation and solvent extraction. Research has involved electrochemistry of cementation and leaching reactions and technology for gold recovery from cyanide and noncyanide leach solutions. Recent research efforts are in the development of magnetic activated carbon for gold recovery and in the analysis of heap leaching technology.

With respect to environmental considerations, research efforts have been made to examine such topics as cleaning of waste coal fuels, air stripping to remove volatile organics from drinking and process water, water disinfection by ozone or chlorine sparging, dispersed oil removal from water, and contaminated soil remediation. Air-sparged hydrocyclone technology has been developed for de-inking flotation in the waste paper recycling industry and for the treatment of contaminated water. A Center of Excellence (COE) has been established for the development of modified activated carbons (MACs).

Finally, an energy research program has been initiated to develop more efficient energy carriers and advanced fuels. This program includes both the development of new catalysts and the use of new reactors for more efficient conversions of raw material (biomass, coal,

oil shale, etc.) into useful products. A major effort in improved technology for dimethyl ether (DME) production is in progress as well as improved technology for production of high density jet fuels.
